WASHINGTON

NACA WARTIME REPORTS are reprints of papers originally issued to provide rapid distribution of advance research results to an authorized group requiring them for the war effort. They were previously held under a security status but are now unclassified. Some of these reports were not technically edited. All have been reproduced without change in order to expedite general distribution.

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF SLOT SHAPE

AND FLAP LOCATION ON THE CHARACTERISTICS OF A LOW-DRAG

AIRFOIL FQUIPPED WITH A 0.25-CHORD SLOTTED FIAP

By Ralph W. Holtzclaw and Yale Weisman

STEMMARY

An investigation was made to determine the offects of slot shape and flap location on the characteristics of an NACA 66,2-216 (a = 0.6) airfoil equipped with a 0.25-chord slotted flap to provide a basis for the study of drooped allerons. Two slots were investigated and practical flap paths were selected for each. One slot had a rounded entry; the other had an entry designed to reduce the gap with the flap retracted to a practical minimum.

Slot shape was found to have a negligible effect on the maximum lift coefficient if the flap was properly located. With the flap deflected, the rounded-entry slot had lower drag coefficients for intermediate lift coefficients than the minimum-gap slot. For either slot, the increment of section pitching-moment coefficient caused by flap deflection was approximately proportional to the increment of section lift coefficient.

With the flap retracted the minimum-gap slot had a lower minimum profile-drag coefficient, low-drag characteristics over a larger range of lift coefficients, and slightly higher section pitching-moment coefficients than the rounded-entry slot.

The flap locations for maximum lift and minimum drag with respect to the airfoil (flap deflected) were further aft and higher with the minimum-gap slot than with the rounded-entry slot.

•

INTRODUCTION

For some time the National Advisory Committee for Accordation has been investigating airfoils equipped with high-lift devices for the purpose of improving the performance characteristics of these airfoils. The results of tests of low-drag airfoils equipped with slotted flaps have been presented in reference 1. The results of reference 2 show that, on convertional airfoils, openings in the airfoil turface caused a reasurable increase in drag of she airfoil for the condition of high-speed flight. It was also found that the location of the flap had a large influence on the magnitude of the maximum obtainable lift coefficients.

To provide a basis for a study of the characteristics of drooped ailprons, the effects of slot shape and flap location on the section aerodynamic characteristics of a low-drag airfoil were determined and practical flap paths were nelocied.

The tests were conducted in the 7- by 10-1000 wind tunnel No. 1 of the Ames Aeromautical Inboratory.

COEFFICIENTS AND CORRECTIONS

The coefficients used in the precentation of results are as follows:

- o₁ section lift coefficient (1/qc)
- Δc_1 increment of section lift coefficient due to flap deflection
- c_{d_n} profile-drag coefficient (d_0/qc)
- c_m section pitching-moment coefficient about quarter chord of section with flap in neutral position (m/qo^2)
- Δc_m increment of section pitching-moment coefficient due to flap deflection

where

- 1 section lift
- d, profile drag
- m section pitching moment

- q dynamic pressure (20V2)
- e airfoil chord including flap

and

- angle of attack for infinite aspect ratio, degrees
- & flap deflection, degrees

The lift, profile-drag, and pitching-moment coefficiente have been corrected for turnel-wall effects. A comparison of force-test results with pressure-distribution measurements of section lift and pitching-moment coefficients indicated negligible end-plate effect on these coefficients. The end-plate effect on the profile-drag coefficients was determined by a comparison of measurements of the loss of momentum in the wing wake with the force-test measurements. All the results have been corrected for this effect.

MODEL AND APPARATUS

The mirfoil was constructed of laminated mahogany to the NACA 66,2-216 (a = 0.6) profile of 4-foot chord. The mirfoil ordinates are given in table I. The aft 0.35 chord of the mirfoil was made removable to allow the testing of different slots. The mirfoil and flam were equipped with a single row of pressure orifices built into the upper and lower surfaces at the midspan station. The orifice locations are listed in table II. The flap was constructed of laminated mahogany to conform to the profile of the normal mirfoil section. The flap ordinates are given in table III. The details of the two slots tested are shown in figure 1. Slot A had a rounded entry, while slot B had an entry designed to reduce the gap with the flap retracted to a practical minimum. The slots will be referred to by their letter designations throughout the remainder of this report.

TEST INSTALLATION

The airfoil was mounted vertically in the 7- by 10-foot wind tunnel No. 1 completely spanning the height of the tunnel, as shown in figure 2. Turntables, 6 feet in diameter, were attached rigidly to the model and mounted flush with the tunnel floor and ceiling. Provisions were made for changing the angle of attack, flap deflection, and the normal and chordwise location of the flap

while the turnel was in operation.

TELT3

The tests were conducted at a dynamic pressure of 50 pounds: per square foot, corresponding to a Reynolds number of approximately 5,100,000 (Mach number of approx. 0.19). Lift, drag, and pitching—moment measurement were made chroughout the useful angle-of-attack range for a constant flup deflection and position. An everage of 20 flap locations was investigated with each slot for flap deflections of 0°, 10°, 20°, 30°, 40°, and 50°. A very limited number were also investigated for 45°. Due to the high loads imposed upon the balance system and the nature of the stall of the model, very few test points were obtained after the stall. The meximum lift, however, was measured for every flap location.

RESULTS AND DISCUSSION

The results of tests to determine the effects of alct shape and flap location on the characteristics of a low-drag airfoil equipped with a 0.25-chord slotted flap are presented as contours of the rose position of the flap for constant lift and drag coefficients. The reference point for these contours was waker as the intersection of the airfoil chord line and the flap nose with the flap retracted (station 0.755 chord on the chord line).

The variation of maximum lift coefficient with flap location and deflection is shown in figure 3 for slot A and in figure 4 for slot B. The flap location with respect to the airfoil for maximum lift at a given deflection is further aft and higher with slot B than with slot A. The maximum measured lift coefficient was 2.89 with slot A (fig. 3(d)) and 2.90 with slot B (fig. 4(d)). The difference between those values is within the experimental accuracy of the tests. Both maximum values were measured with 40° flap deflection. Due to time limitations, the maximum possible lift coefficient was not measured for all flap deflections.

The lift coefficients for which the contours of constant drag coefficients are presented were selected to cover the range of lift coefficients for which the drag coefficient is decreased by flap deflection. Those data are presented for various flap deflections with slot A in figure 5 and with slot B in figure 6. As in the case of the maximum lift coefficient, the flap location for minimum drag, at a giver deflection and lift coefficient, is further

aft and higher with slot B than with slot A. The measured minimum drag coefficients for intermediate lift coefficients are lower with slot A than with slot B. This is probably the result of smoother flow through the slot with the rounded entry.

Complete a rody, amic characteristics of the airfoil with slot A are shown in Tigure 7 for the flap path described by figure 8. For this path the flap is simply hinged about a point 80.25-percent wing chord from the leading edge of the airfoil and 8-percent wing chord below the chord line. The characteristics of the airfoil with slot B are shown in figure 9 for the flap path described by figure 10. For this path the flap nose moves aft and up along a straight line with the flap deflection increasing as the flap is extended. These flap raths were chosen with a view toward a gractical installation. Sufficient data have been presented in the form of contours (figs. 3 to 6) to estimate the maximum lift and drag characteristics for alternate flap paths.

Envelope polars for the two flap paths are shown in figure 11. Data for the plain airfeil as taken from reference 1 are also shown for comparison. As shown by this figure, lower profile drag was obtained with slot A than with slot B for lift coefficients from 0.65 to 2.65. The irregularities in these curves are caused by a shift of the low-drag range with flap deflection (figs. 7 and 9).

A comparison of the maximum lift-coefficient increments due to flap deflection for the two flap paths is shown in figure 12. For further comparison, curves are shown for the maximum lift-coefficient increments measured with the two slots. As shown by figure 12, and figures 3 and 4, the maximum measured lift coefficient was obtained at a flap deflection of 40° for both slots. It should be re-emphasized that a limited number of points were taken for the contours so that the maximum obtainable lift was not measured for every flap deflection, particularly for the low deflections.

As illustrated by figure 13, the increments of section pitching-moment coefficient due to flap deflection are approximately proportional to the increments of section lift coefficient. The variation shown is for zero angle of attack for the selected flap paths.

A comparison of the section aerodynamic characteristics of the airfoil, with the slotted flap undeflected, with the . . characteristics of the plain wing as taken from reference 1 is shown in figure 14. As shown by this figure, the drug increment due to the addition of the slot was considerably higher with slot A

than with elot B. The minimum profile-drag coefficient was 0.0055 with slot A and 0.004? with slot B as compared to 0.0040 for the plain mirroil. The runge of lift coefficients for which low-drag oberacteristics were apparent was larger with slot B than with slot A (fig. 14).

CONCLUDING REMARKS

The results of the tests to determine the effects of slot shape and flap location on the characteristics of a low-drag airfoil equipped with a 0.25-chord clotted flap indicated the following:

- 1. Slow shape had a nogligible effect on the maximum lift coefficient for the two sloss tested if the flap was properly located.
- 2. For intermediate lift coefficients with the flap deflected, the rounded-entry slot had lower profile drag.
- 3. For either slot the increment of section pitching-moment coefficient due to flap deflection was approximately proportional to the increment of section lift coefficient.
- 4. The addition of the minimum gap clow to the plain airfoil caused an increase in the section profile-drag coefficient of 0.0002 (flap retracted), while the addition of the rounded-entry slot caused an increase of 0.0015.
- 5. Low drag was obtained for a larger range of lift coefficients with the minimum-gap slot (flap retracted) than with the rounded-entry slot.
- 6. The pitching-moment coefficients were slightly higher with the minimum-gap slow (flap retracted) than with the rounded-entry slot.
